# Describing a fluid in three-dimensional circular motion with one independent variable by rectangular coordinate 

Valdir Monteiro dos Santos Godoi<br>valdir.msgodoi@gmail.com

#### Abstract

Describe a fluid in three-dimensional circular motion with one independent variable by rectangular coordinate and concludes on the breakdown of Euler and Navier-Stokes equations.

In [1] we showed that the three-dimensional Euler $(v=0)$ and Navier-Stokes equations in rectangular coordinates need to be adopted as
(1) $\frac{\partial p}{\partial x_{i}}+\frac{\partial u_{i}}{\partial t}+\sum_{j=1}^{3} \alpha_{j} \frac{\partial u_{i}}{\partial x_{j}}=v \nabla^{2} u_{i}+\frac{1}{3} v \nabla_{i}(\nabla \cdot u)+f_{i}$,
for $i=1,2,3$, where $\alpha_{j}=\frac{d x_{j}}{d t}$ is the velocity in Lagrangian description and $u_{i}$ and the partial derivatives of $u_{i}$ are in Eulerian description, as well as the scalar pressure $p$ and density of external force $f_{i}$. The coefficient of viscosity is $v$ and by ease we prefer to use the mass density $\rho=1$ (otherwise substitute $p$ by $p / \rho$ and $v$ by $v / \rho$ ).

An alternative equation is

$$
\begin{equation*}
\frac{\partial p_{i}}{\partial x_{i}}+\frac{\partial u_{i}}{\partial t}+\sum_{j=1}^{3} \alpha_{j} \frac{\partial u_{i}}{\partial x_{j}}=v \nabla^{2} u_{i}+\frac{1}{3} v \nabla_{i}(\nabla \cdot u)+f_{i} \tag{2}
\end{equation*}
$$

thus making the pressure a vector: $p=\left(p_{1}, p_{2}, p_{3}\right)$. In both equations is valid
(3) $\frac{D u_{i}}{D t}=\frac{D u_{i}^{E}}{D t}=\frac{D u_{i}^{L}}{D t}=\left.\left(\frac{\partial u_{i}}{\partial t}+\sum_{j=1}^{3} \alpha_{j} \frac{\partial u_{i}}{\partial x_{j}}\right)\right|_{L}$,
where the upper letter $E$ refers to Eulerian velocity and $L$ to Lagrangian velocity. The symbol $\left.\right|_{L}$ means the respective calculation in Lagrangian description, substituting each $x_{i}$ as a function of time, initial value and eventually some parameters.

A condition indicated by us in [1] were

$$
\left\{\begin{array}{c}
\frac{\partial u_{i}}{\partial x_{j}}=0, \quad i \neq j  \tag{4}\\
\partial x_{i}=u_{i} \partial t
\end{array}\right.
$$

because we have, by definition,
(5) $\quad u_{i}=\frac{d x_{i}}{d t}$,
in Lagrangian description, and for this reason the velocity $u_{i}$, a priori, is not dependent of others variables $x_{j}$, with $x_{j} \neq x_{i}$. More than a rigorous mathematical proof, this is a practical approach, which simplifies the original system.

It is very easy to accept the first equation of (4) when there is no link between the spatial coordinates during the movement of the fluid over time, but in a circular motion, for example, it seems to be no longer valid.

Let a circular motion of radius $R$, centered at $\left(x_{C}, y_{C}\right)$ and with constant angular velocity $\omega>0$ described by the equations:

$$
\left\{\begin{array}{l}
x=x_{C}+R \cos \left(\theta_{0}+\omega t\right)  \tag{6}\\
y=y_{C}+R \sin \left(\theta_{0}+\omega t\right)
\end{array}\right.
$$

and consequently

$$
\begin{equation*}
\left(x-x_{C}\right)^{2}+\left(y-y_{C}\right)^{2}=R^{2} \tag{7}
\end{equation*}
$$

Then the velocity components are

$$
\left\{\begin{array}{l}
\alpha_{1}=u_{1}^{L}=\dot{x}=-\omega R \sin \left(\theta_{0}+\omega t\right)=-\omega\left(y-y_{C}\right)=u_{1}^{E}  \tag{8}\\
\alpha_{2}=u_{2}^{L}=\dot{y}=+\omega R \cos \left(\theta_{0}+\omega t\right)=+\omega\left(x-x_{C}\right)=u_{2}^{E}
\end{array}\right.
$$

and the acceleration components are

$$
\left\{\begin{array}{l}
\frac{D u_{1}^{L}}{D t}=\ddot{x}=-\omega^{2} R \cos \left(\theta_{0}+\omega t\right)=-\omega^{2}\left(x-x_{C}\right)=\frac{D u_{1}^{E}}{D t}  \tag{9}\\
\frac{D u_{2}^{L}}{D t}=\ddot{y}=-\omega^{2} R \sin \left(\theta_{0}+\omega t\right)=-\omega^{2}\left(y-y_{C}\right)=\frac{D u_{2}^{E}}{D t}
\end{array}\right.
$$

Supposing that the particles of fluid obey the motion described by (6) to (9), we have

$$
\begin{cases}\frac{\partial u_{1}}{\partial y}=-\omega, & \frac{\partial u_{1}}{\partial x}=0  \tag{10}\\ \frac{\partial u_{2}}{\partial x}=+\omega, & \frac{\partial u_{2}}{\partial y}=0\end{cases}
$$

apparently in disagree with (4) if $\omega \neq 0$. But, as $x$ is a function of $y$ and reciprocally, in this circular motion according (7), again (4) turns valid, for any signal of $x$ and $y$. For to complete a three-dimensional description, we define $z=z_{0}$, without dependence of time, and $u_{3}=0$.

This is a motion of velocity without potential, because $\frac{\partial u_{i}}{\partial x_{j}} \neq \frac{\partial u_{j}}{\partial x_{i}}$ for some $i \neq j$, but if $f=\left(f_{1}, f_{2}, f_{3}\right)$ has potential we have $\frac{\partial S_{i}}{\partial x_{j}}=\frac{\partial S_{j}}{\partial x_{i}}$ for all $i, j=1,2,3$, with

$$
\begin{equation*}
S_{i}=-\frac{\partial u_{i}}{\partial t}-\sum_{j=1}^{3} \alpha_{j} \frac{\partial u_{i}}{\partial x_{j}}+v \nabla^{2} u_{i}+\frac{1}{3} v \frac{\partial}{\partial x_{i}}(\nabla \cdot u)+f_{i} \tag{11}
\end{equation*}
$$

then the system (1) has solution.
The scalar pressure of this motion is

$$
\begin{align*}
p= & \int_{L}\left(S_{1}, S_{2}, S_{3}\right) \cdot d l=\int_{L}\left(-\frac{D u}{D t}+f\right) \cdot d l  \tag{12}\\
= & \omega^{2}\left[\left.\left(\frac{x^{2}}{2}-x_{C} x\right)\right|_{x_{0}} ^{x}+\left.\left(\frac{y^{2}}{2}-y_{C} y\right)\right|_{y_{0}} ^{y}\right]+U+\theta(t) \\
= & \omega^{2}\left[\left(\frac{x^{2}}{2}-x_{C} x\right)-\left(\frac{x_{0}^{2}}{2}-x_{C} x_{0}\right)+\left(\frac{y^{2}}{2}-y_{C} y\right)-\left(\frac{y_{0}^{2}}{2}-y_{C} y_{0}\right)\right]+ \\
& U+\theta(t)
\end{align*}
$$

where $f=\nabla U$ and $L$ is any smooth path linking a point $\left(x_{0}, y_{0}, z_{0}\right)$ to $(x, y, z)$. We can ignore the use of $x_{0}$ and $y_{0}$ and use only the free function for time, $\theta(t)$, which on the other hand can include the terms in $x_{0}$ and $y_{0}$, and nevertheless this solution shows us that the pressure is not uniquely well determined, therefore we get to the negative answer to Smale's $15^{\text {th }}$ problem, according already seen in [2] and [3], even if we assign the velocity value on some surface that we wish and even if $\theta(t)$ does not depend explicitly on the variable time $t$. In this motion the pressure is dependent, besides $x_{C}, y_{C}$ and $\omega$, specific parameters of the movement conditions of a particle, of $\theta(t)$ and more two parameters, $x_{0}$ and $y_{0}$, then there is not uniqueness of solution.

Note that in order to continue using the traditional form of the Euler and Navier-Stokes equations we will have non-linear equations, which can make it difficult to obtain the solutions and bring all the difficulties that we know. To make sense to use the velocity in Eulerian description rather than the Lagrangian description in $\alpha_{j}$ it is necessary that, for all $t \geq 0$,

$$
\begin{equation*}
u^{E}(x(t), y(t), z(t), t)=\alpha(t)=\left(\frac{d x}{d t}, \frac{d y}{d t}, \frac{d z}{d t}\right)=u^{L}(t) \tag{13}
\end{equation*}
$$

omitting the use of possible parameters of motion, then nothing more natural than the definitive substitution of the terms $\frac{\partial u_{i}}{\partial t}+\sum_{j=1}^{3} \alpha_{j} \frac{\partial u_{i}}{\partial x_{j}}$, as well as $\frac{\partial u_{i}}{\partial t}+\sum_{j=1}^{3} u_{j} \frac{\partial u_{i}}{\partial x_{j}}$ in the traditional form, by $\frac{D u_{i}^{L}}{D t}$ or $\frac{D \alpha_{i}}{D t}$. This brings a great and important simplification in the equations, and to return to having the position as reference it is enough to use the conversion or definition adopted for $x(t), y(t)$ and $z(t)$, including the possible additional parameters, for example, substituting initial positions in function of position and time, etc.

Thus, more appropriate Euler $(v=0)$ and Navier-Stokes equations with scalar pressure are, in index notation,

$$
\begin{equation*}
\frac{\partial p}{\partial x_{i}}+\frac{D \alpha_{i}}{D t}=v \nabla^{2} u_{i}+\frac{1}{3} v \frac{\partial}{\partial x_{i}}(\nabla \cdot u)+f_{i} \tag{14}
\end{equation*}
$$

If $v=0$ and $f$ is not conservative then there is not solution for Euler equations, as well as if $u$ is conservative and $f$ is not conservative there is no solution for NavierStokes equations, which now it is very clear to see from (14) and it is according [4]. More specifically, if $u^{0}$, the initial velocity, is conservative (irrotational or potential flow) and $f$ is not conservative then there is no solution for Navier-Stokes equations, because it is impossible to obtain the pressure. This then solve [5] for the cases (C) and (D), the breakdown of solutions, for both $u^{0}$ and $f$ belonging to Schwartz Space in case (C), and smooth functions with period 1 in the three orthogonal directions $e_{1}, e_{2}, e_{3}$ in case (D). As $u^{0}$ need obey to the incompressibility condition, $\nabla \cdot u^{0}=0$, with $\nabla \times u^{0}=0$ and $u^{0}=\nabla \varphi^{0}$, where $\varphi^{0}$ is the potential of $u^{0}$, we have $\nabla^{2} u^{0}=0$ and $\nabla^{2} \varphi^{0}=0$, i.e., $u^{0}$ and $\varphi^{0}$ are harmonic functions, unlimited functions except the constants, including zero. As $u^{0}$ need be limited, we choose $u^{0}=0$ for case (C) (where it is necessary that $\int_{\mathbb{R}^{3}}\left|u^{0}\right|^{2} d x d y d z$ is finite) and any constant for case (D), of spatially periodic solutions. In case (D) the external force need belonging to Schwartz Space with relation to time.

Note that the application of a non conservative force in fluid is naturally possible and there will always be some movement, even starting from rest. So that this is not a paradoxical situation it seems certain that the pressure in this case cannot be scalar, but rather vector, and thus the equation returns to solution in all cases (assuming all derivatives are possible, etc.). It is as indicated in (2), or substituting $p$ by $p_{i}$ in (14).
